
Queue at decision time t_n

front → back $Q = 6$ lots resting

Queue at insertion time a_n

$Q_o = 8$ lots ahead, unknown at t_n and so forecast by the model

Markout: $m_o(h) = s\left(\mathrm{mid}(a_o + T_o + h) - p_o\right)$, measured from the fill, with $s = +1$ for a bid and -1 for an ask.
